CME 241: Reinforcement Learning for Finance

January 17, 2020

Problem 1.

Work out (in L^AT_EX) the equations for Absolute/Relative Risk Premia for CARA/CRRA respectively

Solution.

(1) Since risk premia are closely related to one's utility of money, calculate the risk premia, we can perform taylor-expansion on utility $U(x)$ like follows:

$$U(x) \approx U(\bar{x}) + U'(\bar{x}) \cdot (x - \bar{x}) + \frac{1}{2} U''(\bar{x}) \cdot (x - \bar{x})^2 \quad (1)$$

$$U(x_{CE}) \approx U(\bar{x}) + U'(\bar{x}) \cdot (x_{CE} - \bar{x}) \quad (2)$$

Since we have $\mathbb{E}[U(x)] = U(x_{CE})$, the left hand side is the expectation of $U(x)$:

$$\mathbb{E}[U(x)] \approx U(\bar{x}) + \frac{1}{2} \cdot U''(\bar{x}) \cdot \sigma_x^2 = U(x_{CE}) \approx U(\bar{x}) + U'(\bar{x}) \cdot (x_{CE} - \bar{x}) \quad (3)$$

$$U'(\bar{x}) \cdot (x_{CE} - \bar{x}) \approx \frac{1}{2} \cdot U''(\bar{x}) \cdot \sigma_x^2 \quad (4)$$

Moving $U'(\bar{x})$ to the right-hand side (RHS) and U'' to the left-hand side (LHS) of the equation, we have:

$$x_{CE} - \bar{x} \approx \frac{1}{2} \cdot \frac{U''(\bar{x})}{U'(\bar{x})} \cdot \sigma_x^2 \quad (5)$$

$$\pi_A = \bar{x} - x_{CE} \approx -\frac{1}{2} \cdot A(\bar{x}) \cdot \sigma_x^2, \quad (6)$$

where $A(\bar{x}) = \frac{U''(\bar{x})}{U'(\bar{x})}$.

For Constant Absolute Risk-Aversion (CARA), consider the utility function $U(x) = \frac{-e^{-ax}}{a}$:

$$U'(\bar{x}) = e^{-a\bar{x}} \quad (7)$$

$$U''(\bar{x}) = -a \cdot e^{-a\bar{x}} \quad (8)$$

$$\frac{U''(\bar{x})}{U'(\bar{x})} = -a \quad (9)$$

Plug it into the π_A equation before, we have:

$$\pi_A = \mu - x_{CE} = -\frac{1}{2} \cdot A(\bar{x}) \cdot \sigma_x^2 = \frac{a\sigma^2}{2} \quad (10)$$

where μ is the expected value of the uncertain payment and x_{CE} is the value of certainty equivalent.

Certainty equivalent refers to the amount that a person is willing to pay; in a risk-avert scenario, this value is typically lower than μ .

(2) For Constant Relative Risk-Aversion (CRRA), consider $U(x) = \frac{x^{1-\gamma}}{1-\gamma}$:

$$R(x) = \frac{-U'' \cdot x}{U(x)} = \gamma \quad (11)$$

When $\gamma \neq 1$:

$$\mathbb{E}[U(x)] = \frac{e^{\mu(1-\gamma) + \frac{\sigma^2}{2}(1-\gamma)^2}}{1-\gamma} \quad (12)$$

$$= \frac{e^{(1-\gamma) \cdot (\mu + \frac{\sigma^2}{2}(1-\gamma))}}{1-\gamma} \quad (13)$$

Therefore:

$$x_{CE} = e^{\mu + \frac{\sigma^2}{2}(1-\gamma)} \quad (14)$$

$$\pi_R = 1 - \frac{x_{CE}}{\bar{x}} = 1 - \frac{x_{CE}}{\frac{e^{\mu + \frac{\sigma^2}{2}}}{1 - e^{-\frac{\sigma^2 \gamma}{2}}}} \quad (15)$$

$$= 1 - e^{-\frac{\sigma^2 \gamma}{2}} \quad (16)$$
